Problem 1: Textbook RSA and hybrid encryption

A common variant of textbook RSA is the following: During key generation, the modulus $N$ is chosen as usual. We chose $e$ as $e := 3$ (instead of random). Then $d$ is chosen with $ed \equiv 1 \mod \varphi(N)$ (as usual). This is implemented by the Python functions rsa_keygen, rsa_enc, rsa_dec below.

We use this in a “hybrid encryption”, which first picks an AES key $k$, encrypts it with RSA, and then encrypts the actual message with AES using the key $k$. (Functions hyb_enc, hyb_dec.)

Your task is to write an adversary that, given the public key $pk$, and the hybrid encryption $c$ of some message $m$, finds $m$. That is, fill in the function body of the function adv below so that the function test_adv prints Success. The adversary broke the scheme.

**Hint:** Note that $k < \sqrt[3]{N}$ here. This makes it much simpler to find $k$ given $k^3 \mod N$!

(You find the following file on the lecture webpage, too.)

```python
#!/usr/bin/python3

# Use "pip install sympy" (possibly with sudo) to install sympy
# And "Crypto" might need "pip install pycrypto" if it's not installed

import sympy, math, Crypto, random

prime_len = 1024

def egcd(a, b):
    if a == 0:
        return (b, 0, 1)
    else:
        g, y, x = egcd(b % a, a)
        return (g, x - (b // a) * y, y)

def modinv(a, m):
    g, x, y = egcd(a, m)
    if g != 1:
        raise Exception('modular inverse does not exist')
    else:
```

```
return x % m

def rsa_keygen():
    while True:
        try:
            p = sympy.ntheory.generate.randprime(2**prime_len,2**(prime_len+1))
            q = sympy.ntheory.generate.randprime(2**prime_len,2**(prime_len+1))
            e = 3
            N = p*q
            phiN = (p-1)*(q-1)
            pk=(N,e)
            sk=(N,modinv(e,phiN))
            return (pk,sk)
        except Exception as e:
            pass

# Rough ad-hoc algorithm, not optimized

    # Call the adversary, let him guess m
    m2 = adv(pk, c)
    assert isinstance(m2, bytes)
    # Check
    if m == m2:
        print("Success. The adversary broke the scheme")
    else:
        print("*** Failure ***")

test_adv()

Problem 2: Malleability of textbook RSA

The adversary get a textbook RSA encryption $c = E(pk, m)$ for some unknown message $m$. The adversary also knows $pk = (N, e)$. The adversary wants to compute $c' = E(pk, 2m)$. (This is a specific example of malleability.) How can the adversary efficiently compute $c'$ from $c$ and $pk$?

You may assume that $0 \leq m < N/2$.
